### Animal Models For The Study

The most common animal model for the study of MS is experimental allergic encephalitis (EAE), which depending upon the host animal can present as relapsing/remitting or progressive disease. Although EAE has provided mechanistic insights implicating T-cell activation in the onset and progression of disease, understanding the mechanisms of pathology onset and myelin repair in the CNS require ...

Purpose: Animal models have contributed greatly to the study of voice, permitting the examination of laryngeal biology and the testing of surgical, medical, and behavioral interventions. Various models have been used. However, until recently, the mouse (*Mus musculus*) has not been used in laryngeal research, and features of the mouse larynx have not been defined.

We also found that a pdm09 virus and a seasonal H1N1 virus, as well as one of the H3N2 viruses, but not a type B virus tested, are transmitted by the airborne route in these hamsters. Syrian hamsters thus have the potential to be used as a small-animal model for the study of human influenza viruses.

There is an increased interest in studying these viruses in animal models to gain a deeper understating not only of viral pathogenesis, but also for the evaluation of medical countermeasures (MCM) to mitigate disease threats. In this review, we examine current knowledge regarding animal models employed in the study of these viruses.

A 2000 study found that animal models concorded (coincided on true positives and false negatives) with human toxicity in 71% of cases, with 63% for nonrodents alone and 43% for rodents alone. In 1987, Davidson et al. suggested that selection of an animal model for research be based on nine considerations.

Small species such as rabbits, rats and mice are by far the most popular and convenient species to study as animal models of tendinosis. Rabbits are popular as their cellular and tissue physiology approximates that of humans 27 and they are mild-tempered and relatively easy to handle.
